

OPTIMAL CONTROL OF UNDERACTUATED MECHANICAL SYSTEMS: A GEOMETRIC APPROACH

LEONARDO COLOMBO, DAVID MARTÍN DE DIEGO, AND MARCELA ZUCCALLI

ABSTRACT. In this paper, we consider a geometric formalism for optimal control of under-actuated mechanical systems. Our techniques are an adaptation of the classical Skinner and Rusk approach for the case of Lagrangian dynamics with higher-order constraints. We study a regular case where it is possible to establish a symplectic framework and, as a consequence, to obtain a unique vector field determining the dynamics of the optimal control problem. These developments will allow us to develop a new class of geometric integrators based on discrete variational calculus.

1. INTRODUCTION

The mathematical activity in the last century in dynamical systems, mechanics and related areas has been extraordinary. The number of applications has grown exponentially and both basic science as well as several engineering technologies are profiting from this development. In the 1960s more sophisticated and powerful techniques coming from modern differential geometry and topology have been introduced in their study, experiencing a spectacular growth in the last 50 years. Control and optimal control of mechanical systems has not ignored these developments, becoming now a principal research focus of nonlinear control theory. In particular, there are an increasing interest in the control of underactuated mechanical systems (see [10, 13]). These type of mechanical systems are characterized by the fact that there are more degrees of freedom than actuators. This type of system is quite different from a mathematical and engineering perspective than fully actuated control systems where all the degrees of freedom are actuated.

The class of underactuated mechanical systems are abundant in real life for different reasons, for instance, as a result of design choices motivated by the search of less cost engineering devices or as a result of a failure regime in fully actuated mechanical systems. The underactuated systems include spacecraft, underwater vehicles, mobile robots, helicopters, wheeled vehicles, mobile robots, underactuated manipulators...

On the other hand, there are many papers in which optimal control problems are addressed using geometric techniques (see, for instance, [8, 18, 19, 31] and references therein). Now, we introduce an optimization strategy in an underactuated mechanical system, that is, we are interested in studying the implementation of devices in which a controlled quantity is used to influence the behavior of the undeactuated system in order to achieve a desired goal (control) using the most economical strategy (optimization). Thus, in our paper we develop a new geometric setting for optimal control of underactuated lagrangian systems strongly inspired on the Skinner and Rusk formulation for singular Lagrangians systems [30]. Since in this setting the controlled Euler-Lagrange equation are second-order differential equations we will need to implement an higher-order version of this classical Skinner and Rusk formalism [5]. This geometric procedure gives us an intrinsic version of the differential equations for optimal trajectories and permits us to detect the preservation of geometric properties (symplecticity, preservation of the hamiltonian,

etc.). For expository simplicity, we restrict ourselves in Section 5 to the so-called optimal control of superarticulated mechanical systems, in which only some of the degrees of freedom are controlled directly, with the remaining variables freely evolving subject only to dynamic interactions with the actuated degrees of freedom (see [2, 29]). Obviously, our theory can be easily extended to more general class of underactuated lagrangian systems.

Moreover, using a discrete version of this variational approach to optimal control of underactuated lagrangian systems it is possible to construct discretization schemes for this type of systems which preserve a discrete symplectic form. All this type of geometric integrators has demonstrated, in worked examples, an exceptionally good longtime behavior and obviously this research is of great interest from numerical and geometric considerations (see [17]).

The paper is organized as follows. In Section 2 we recall some geometric constructions and properties of higher-order tangent bundles to make the paper self-contained. In section 3, we derive the main geometric objects of higher-order variational calculus with higher-order constraints. In Section 4, we deduce the geometric framework for higher-order mechanics using the Skinner and Rusk formalism. In Section 5 we apply the previous techniques to the case of optimal control of underactuated Lagrangian systems. A concrete example: the Cart-Pole system is carefully analyzed. Finally, in Section 6 we derive the corresponding discrete version obtaining a numerical integrator which inherits some of the previously analyzed geometric properties of the continuous optimal control problem for the underactuated system (symplecticity, momentum preservation...).

2. HIGHER-ORDER TANGENT BUNDLES

In this section we recall some basic facts of the higher-order tangent bundles theory. For more details see [15, 21].

Let Q be a manifold of dimension n . An equivalence relation is introduced in the set $C^\infty(\mathbb{R}, Q)$ of differentiable curves from $\mathbb{R}$ to Q . By definition, two given curves in Q $\gamma_1(t)$ and $\gamma_2(t)$ where $t \in (-a, a)$ with $a \in \mathbb{R}$ have contact of order k at $q_0 = \gamma_1(0) = \gamma_2(0)$ if there is a local chart (φ, U) of Q such that $q_0 \in U$ and

$$\left. \frac{ds}{dt} (\varphi \circ \gamma_1(t)) \right|_{t=0} = \left. \frac{ds}{dt} (\varphi \circ \gamma_2(t)) \right|_{t=0},$$

for $s = 0, \dots, k$. This is a well defined equivalence relation in $C^\infty(\mathbb{R}, Q)$ and the equivalence class of a curve γ will be denoted by $[\gamma]_0^{(k)}$. The set of equivalence classes will be denoted by $T^{(k)}Q$ and we can see that it is a differentiable manifold. Moreover, $\tau_Q^k : T^{(k)}Q \rightarrow Q$ where $\tau_Q^k \left([\gamma]_0^{(k)} \right) = \gamma(0)$ is a fiber bundle called the *tangent bundle of order k* of Q .

We also may define the surjective mappings $\tau_Q^{(l,k)} : T^{(k)}Q \rightarrow T^{(l)}Q$, for $l \leq k$, given by $\tau_Q^{(l,k)} \left([\gamma]_0^{(k)} \right) = [\gamma]_0^{(l)}$. It is easy to see that $T^{(1)}Q \equiv TQ$, the tangent bundle of Q , $T^{(0)}Q \equiv Q$ and $\tau_Q^{(0,k)} = \tau_Q^k$.

Given a differentiable function $f : Q \rightarrow \mathbb{R}$ and $l \in \{0, \dots, k\}$, its l -lift $f^{(l,k)}$ to $T^{(k)}Q$, $0 \leq l \leq k$, is the differentiable function defined as

$$f^{(l,k)}([\gamma]_0^{(k)}) = \left. \frac{d^l}{dt^l} (f \circ \gamma(t)) \right|_{t=0}.$$

Of course, these definitions can be applied to functions defined on open sets of Q .

From a local chart (q^i) on a neighborhood U of Q , it is possible to induce local coordinates $(q^{(0)i}, q^{(1)i}, \dots, q^{(k)i})$ on $T^{(k)}U = (\tau_Q^k)^{-1}(U)$, where $q^{(s)i} = (q^i)^{(s,k)}$ if $0 \leq s \leq k$. Sometimes, we will use the standard conventions, $q^{(0)i} \equiv q^i$, $q^{(1)i} \equiv \dot{q}^i$ and $q^{(2)i} \equiv \ddot{q}^i$.

Given a vector field X on Q , we define its k -lift $X^{(k)}$ to $T^{(k)}Q$ as the unique vector field on $T^{(k)}Q$ satisfying the following identities

$$X^{(k)}(f^{(l,k)}) = (X(f))^{(l,k)}, \quad 0 \leq l \leq k,$$

for all differentiable function f on Q . In coordinates, the k -lift of a vector field $X = X^i \frac{\partial}{\partial q^i}$ is

$$X^{(k)} = (X^i)^{(s,k)} \frac{\partial}{\partial q^{(s)i}}.$$

Now, we consider the canonical immersion $j_k : T^{(k)}Q \rightarrow T(T^{(k-1)}Q)$ defined as $j_k([\gamma]_0^{(k)}) = [\gamma^{(k-1)}]_0^{(1)}$, where $\gamma^{(k-1)}$ is the lift of the curve γ to $T^{(k-1)}Q$; that is, the curve $\gamma^{(k-1)} : \mathbb{R} \rightarrow T^{(k-1)}Q$ is given by $\gamma^{(k-1)}(t) = [\gamma_t]_0^{(k-1)}$ where $\gamma_t(s) = \gamma(t+s)$. In local coordinates

$$j_k(q^{(0)i}, q^{(1)i}, q^{(2)i}, \dots, q^{(k)i}) = (q^{(0)i}, q^{(1)i}, \dots, q^{(k-1)i}; q^{(1)i}, q^{(2)i}, \dots, q^{(k)i}).$$

We use the map j_k to construct the differential operator d_T which maps a function f on $T^{(k)}Q$ into a function $d_T f$ on $T^{(k+1)}Q$

$$d_T f([\gamma]_0^{k+1}) = j_{k+1}([\gamma]_0^{k+1})(f).$$

3. VARIATIONAL CALCULUS WITH HIGHER-ORDER CONSTRAINTS

In this section, we briefly review the main notions of variational calculus with higher-order constraints.

Let us consider a mechanical system whose dynamic is described by a Lagrangian $L : T^{(k)}Q \rightarrow \mathbb{R}$ that depends on higher-order derivatives up to order k . Given two points $x, y \in T^{(k-1)}Q$ we define the infinite-dimensional manifold $\mathcal{C}^{2k}(x, y)$ of $2k$ -differentiable curves which connect x and y as

$$\mathcal{C}^{2k}(x, y) = \{c : [0, T] \rightarrow Q \mid c \text{ is } C^{2k}, c^{(k-1)}(0) = x \text{ and } c^{(k-1)}(T) = y\}.$$

Fixed a curve c in $\mathcal{C}^{2k}(x, y)$, the tangent space to $\mathcal{C}^{2k}(x, y)$ at c is given by

$$\begin{aligned} T_c \mathcal{C}^{2k}(x, y) &= \{X : [0, T] \rightarrow TQ \mid X \text{ is } C^{2k-1}, X(t) \in T_{c(t)}Q, \\ &\quad X^{(k-1)}(0) = 0 \text{ and } X^{(k-1)}(T) = 0\}. \end{aligned}$$

Let us consider the *action functional* $\mathcal{A}$ on C^{2k} -curves in Q given by

$$\begin{aligned} \mathcal{A} : C^{2k}(x, y) &\longrightarrow \mathbb{R} \\ c &\longmapsto \int_0^T L(c^{(k)}(t)) dt. \end{aligned} \tag{3.1}$$

Definition 3.1. Hamilton's principle. A curve $c \in \mathcal{C}^{2k}(x, y)$ is a solution of the Lagrangian system determined by $L : T^{(k)}Q \rightarrow \mathbb{R}$ if and only if c is a critical point of $\mathcal{A}$.

In order to find the critical points of $\mathcal{A}$, we need to characterize the curves c such that $d\mathcal{A}(c)(X) = 0$ for all $X \in T_c \mathcal{C}^{2k}(x, y)$. Taking a family of curves $c_\epsilon \in \mathcal{C}^{2k}(x, y)$ with $c_0 = c$ and $\epsilon \in (-b, b) \subset \mathbb{R}$, the stationary condition can be written as

$$\left. \frac{d}{d\epsilon} \right|_{\epsilon=0} \mathcal{A}(c_\epsilon) = 0.$$

Let us denote $\delta c^i = \left. \frac{d}{d\epsilon} \right|_{\epsilon=0} c_\epsilon^i$ and $\delta^{(l)} c^i = \frac{d^l}{dt^l} \delta c^i$; then we deduce the following result (see [24] for the same result when $k = 1$).

Theorem 3.2. Let $L : T^{(k)}Q \rightarrow \mathbb{R}$ be a Lagrangian of order k and $\mathcal{A}(c) = \int_0^T L(c^{(k)}(t)) dt$ the action functional defined on $\mathcal{C}^{2k}(x, y)$. Then, there exists a unique operator $\mathcal{E}L : T^{(2k)}Q \rightarrow T^*Q$ and a unique 1-form Θ_L on $T^{(2k-1)}Q$ such that for all variations $\delta c_\epsilon \in T_c \mathcal{C}^{2k}(x, y)$ we have

$$d\mathcal{A}(c) \cdot \delta c_\epsilon = \int_0^T \mathcal{E}L(c^{(2k)}(t)) \cdot \delta c(t) dt + \left[\Theta_L(c^{(2k-1)}(t)) \cdot \delta^{(2k-1)} c(t) \right]_0^T.$$

$\mathcal{E}L$ is called **Euler-Lagrange operator** and Θ_L is called the **Poincaré-Cartan 1-form**. In local coordinates we have that

$$\begin{aligned}\mathcal{E}L &= \sum_{l=0}^k (-1)^l \frac{d^l}{dt^l} \left(\frac{\partial L}{\partial q^{(l)i}} \right) dq^i, \\ \Theta_L &= \sum_{l=0}^{k-1} \hat{p}_{(l)i} dq^{(l)i},\end{aligned}$$

where the functions $\hat{p}_{(l)i}$ with $0 \leq l \leq k-1$, are the **Jacobi-Ostrogradski generalized momenta** defined by

$$\hat{p}_{(l)i} = \sum_{s=0}^{k-l-1} (-1)^l d_T^s \left(\frac{\partial L}{\partial q^{(l+s+1)i}} \right).$$

The equations of motion of the system, called **higher-order Euler-Lagrange equations**, are locally written as

$$\sum_{l=0}^k (-1)^l \frac{d^l}{dt^l} \left(\frac{\partial L}{\partial q^{(l)i}} \right) = 0, \quad 1 \leq i \leq n.$$

The 1-form Θ_L give rise the exact 2-form $\Omega_L = -d\Theta_L$ on $T^{(2k-1)}Q$ which is called the **Poincaré Cartan 2-form**. In local coordinates

$$\Omega_L = \sum_{l=0}^{k-1} dq^{(l)i} \wedge d\hat{p}_{(l)i}.$$

Is easy to prove that Ω_L is symplectic if and only if

$$\det \left(\frac{\partial^2 L}{\partial q^{(k)i} \partial q^{(k)j}} \right) \neq 0.$$

The higher-order Lagrangian L is called **regular** if the 2-form Ω_L is symplectic. In the following, we will assume that the Lagrangian L is regular.

We will see that introducing higher-order constraints and applying the Lagrangian multipliers Lemma (see, for instance, [1]), it is possible to derive the equations of motion and the corresponding geometric structures associated to this constrained problem.

Let us consider a submanifold $\mathcal{M}$ of $T^{(k)}Q$ locally determined by the vanishing of the constraints functions $\Phi^\alpha : T^{(k)}Q \rightarrow \mathbb{R}$, $1 \leq \alpha \leq m$.

We assume that the restriction of the projection $(\tau_Q^{(k-1,k)})|_{\mathcal{M}} : \mathcal{M} \rightarrow T^{(k-1)}Q$ is a submersion. Locally, this conditions means that the $m \times n$ -matrix

$$\begin{pmatrix} \frac{\partial(\Phi^1, \dots, \Phi^m)}{\partial(q_1^{(k)}, \dots, q_n^{(k)})} \end{pmatrix}$$

is of rank m at all points of $\mathcal{M}$.

Consider now the subset $\mathcal{C}^{2k}(x, y, \mathcal{M})$ of $\mathcal{C}^{2k}(x, y)$ of curves that satisfies these constraint equations, that is

$$\begin{aligned}\mathcal{C}^{2k}(x, y, \mathcal{M}) &= \{c : [0, T] \longrightarrow Q \mid q \text{ is } C^{2k}, c^{(k-1)}(0) = x, \\ &\quad \text{and } c^{(k-1)}(T) = y \text{ and } c^{(k)}(t) \in \mathcal{M} \text{ for all } t \in [0, T]\}.\end{aligned}$$

Definition 3.3. A curve $c \in \mathcal{C}^{2k}(x, y, \mathcal{M})$ will be called a solution of the higher-order variational problem with constraints if c is a critical point of $\mathcal{A}|_{\mathcal{C}^{2k}(x, y, \mathcal{M})}$.

For solving this type of problems we will need the following version of the Lagrange Multipliers Lemma.

Lemma 3.4. *Let $\mathcal{N}$ be a smooth manifold and let $\mathcal{F}$ be a Banach space with $g : \mathcal{N} \rightarrow \mathcal{F}$ a smooth submersion so that $g^{-1}(0)$ is a submanifold of $\mathcal{N}$. Let $f : \mathcal{N} \rightarrow \mathbb{R}$ be a smooth function. Then $x \in g^{-1}(0)$ is critical point of $f|_{g^{-1}(0)}$ if and only if there exists $\lambda \in \mathcal{F}^*$ such that x is a critical point of $f - \lambda \circ g$.*

As in the case of systems with constraints on TQ , by using the Lagrange Multipliers lemma, we may characterize the regular critical points of the higher-order problem with constraints as an unconstrained problem for an extended Lagrangian system. (See [22], for a detailed proof).

Proposition 3.5. (Variational problem with higher-order constraints)

A curve $c \in \mathcal{C}^{2k}(x, y, \mathcal{M})$ is a critical point of the variational problem with higher-order constraints if and only if c is a critical point of the functional

$$\int_0^1 \mathcal{L}(q^{(k)}(t), \lambda(t)) dt,$$

where $\lambda = (\lambda_1, \dots, \lambda_m)$ as regarded as generalized coordinates on $\mathbb{R}^m$ and $\mathcal{L} : T^{(k)}Q \times \mathbb{R}^m \rightarrow \mathbb{R}$ is defined by

$$\mathcal{L}(q^{(0)}, q^{(1)}, \dots, q^{(k)}, \lambda) = L(q^{(0)}, q^{(1)}, \dots, q^{(k)}) - \lambda_\alpha \Phi^\alpha(q^{(0)}, q^{(1)}, \dots, q^{(k)}).$$

Remark 3.6. *The equations*

$$\begin{aligned} \sum_{l=0}^k (-1)^l \frac{d^l}{dt^l} \left(\frac{\partial L}{\partial q^{(l)i}} - \lambda_\alpha \frac{\partial \Phi^\alpha}{\partial q^{(l)i}} \right) &= 0 \quad i = 1, \dots, n, \quad \alpha = 1, \dots, m, \\ \Phi(q^{(0)}, q^{(1)}, \dots, q^{(k)}) &= 0, \end{aligned}$$

are called **Euler-Lagrange equations with higher-order constraints**.

4. GEOMETRIC FORMULATION FOR HIGHER-ORDER CONSTRAINED VARIATIONAL PROBLEMS

Now, we develop a geometric characterization higher-order constrained variational problems using, as an essential tool, the Skinner and Rusk formulation (see [30]).

Let us consider the Whitney sum $T^*(T^{(k-1)}Q) \oplus T^{(k)}Q$ and the canonical projections

$$\begin{aligned} pr_1 : T^*(T^{(k-1)}Q) \oplus T^{(k)}Q &\longrightarrow T^*(T^{(k-1)}Q), \\ pr_2 : T^*(T^{(k-1)}Q) \oplus T^{(k)}Q &\longrightarrow T^{(k)}Q. \end{aligned}$$

Let us take the submanifold $W_0 = pr_2^{-1}(\mathcal{M}) = T^*(T^{(k-1)}Q) \times \mathcal{M}$ and the restrictions to W_0 of the canonical projections pr_1 and pr_2

$$\begin{aligned} \pi_1 &= pr_1|_{W_0} : W_0 \subset T^*(T^{(k-1)}Q) \oplus T^{(k)}Q \rightarrow T^*(T^{(k-1)}Q) \\ \pi_2 &= pr_2|_{W_0} : W_0 \subset T^*(T^{(k-1)}Q) \oplus T^{(k)}Q \rightarrow \mathcal{M}. \end{aligned}$$

Now, we consider on W_0 the presymplectic 2-form

$$\Omega_{W_0} = \pi_1^*(\omega_{T^{(k-1)}Q}),$$

where $\omega_{T^{(k-1)}Q}$ is the canonical symplectic form on $T^*(T^{(k-1)}Q)$. Define also the function $H_{W_0} : W_0 \rightarrow \mathbb{R}$ given by

$$H_{W_0}(\alpha, p) = \langle \alpha, j_k(p) \rangle - L|_{\mathcal{M}}(p)$$

where $(\alpha, p) \in W_0 = T^*(T^{(k-1)}Q) \times \mathcal{M}$. Here $\langle \cdot, \cdot \rangle$ denotes the natural pairing between vectors and covectors on $T^{(k-1)}Q$ (observe that $j_k(p) \in TT^{(k-1)}Q$).

We will see that the dynamics of the higher-order constrained variational problem is intrinsically characterized as the solutions of the presymplectic hamiltonian equation

$$i_X \Omega_{W_0} = dH_{W_0}. \quad (4.1)$$

Let us consider $\Omega = pr_1^*(\omega_{T^{(k-1)}Q})$ and $H : T^*(T^{(k-1)}Q) \oplus T^{(k)}Q \rightarrow \mathbb{R}$ given by

$$H = \langle pr_1, pr_2 \rangle - pr_2^*L = \langle pr_1, pr_2 \rangle - L \circ \pi_2.$$

Observe that locally

$$\ker \Omega = \text{span} \left\langle \mathcal{V}_i = \frac{\partial}{\partial q^{(k)i}} \right\rangle.$$

Then, it is easy to show that equations (4.1) are equivalent to (see [3])

$$\begin{cases} i_X \Omega - dH & \in (TW_0)^0 \\ X & \in TW_0, \end{cases} \quad (4.2)$$

where TW^0 is the annihilator of TW_0 locally spanned by $\{d\Phi^\alpha\}$, where $\Phi^\alpha : W_0 \rightarrow \mathbb{R}$ denote the constraints $\Phi^\alpha = \Phi^\alpha \circ pr_2$ (for notational simplicity, we do not distinguish the notation between constraints on $\mathcal{M}$ and constraints on W_0).

Take coordinates $(q^{(0)i}, q^{(1)i}, \dots, q^{(k-1)i}; p_i^{(0)}, \dots, p_i^{(k-1)}, q^{(k)i})$ in $T^*(T^{(k-1)}Q) \oplus T^{(k)}Q$, then the local expressions of the presymplectic 2-form Ω and the hamiltonian H are

$$\begin{aligned} \Omega &= \sum_{r=0}^{k-1} dq^{(r)i} \wedge dp_i^{(r)}, \\ H &= \sum_{r=0}^{k-1} q^{(r+1)i} p_i^{(r)} - L(q^{(0)i}, q^{(1)i}, \dots, q^{(k)i}). \end{aligned}$$

Consider a vector field X on $T^*(T^{(k-1)}Q) \oplus T^{(k)}Q$ with local expression

$$X = \sum_{r=0}^k X^{(r)i} \frac{\partial}{\partial q^{(r)i}} + \sum_{r=0}^{k-1} Y_i^{(r)} \frac{\partial}{\partial p_i^{(r)}}.$$

The equations (4.2) implies that

$$\begin{aligned} -Y_i^{(0)} &= -\frac{\partial L}{\partial q^{(0)i}} + \lambda_\alpha \frac{\partial \Phi^\alpha}{\partial q^{(0)i}}, \\ -Y_i^{(r)} &= p_i^{(r-1)} - \frac{\partial L}{\partial q^{(r)i}} + \lambda_\alpha \frac{\partial \Phi^\alpha}{\partial q^{(r)i}}, \quad r = 1, \dots, k-1, \\ X_i^{(r)} &= \frac{\partial H}{\partial p_i^{(r)}} = q^{(r+1)i}; \quad r = 0, \dots, k-1. \end{aligned}$$

The solutions of Equation (4.2) are defined on the first constraint submanifold given by the set of points $x \in W_0$ such that $(dH + \lambda_\alpha d\Phi^\alpha)(x)(Z) = 0$, for all $Z \in \ker \Omega(x)$. Locally these restrictions are defined from the following relations

$$\varphi_i^1 = p_i^{(k-1)} - \frac{\partial L}{\partial q^{(k)i}} + \lambda_\alpha \frac{\partial \Phi^\alpha}{\partial q^{(k)i}} = 0, \quad i = 1, \dots, n.$$

The equations $\varphi_i^1 = 0$ (primary relations) determine the set of points W_1 of W_0 where (4.2) has a solution. W_1 is the primary constraint submanifold (assuming that it is a submanifold) for the presymplectic hamiltonian system $(W_0, \Omega_{W_0}, H_{W_0})$. (See, for instance, [16]).

Then, we have two different types of equations which restrict the dynamics on $T^*(T^{(k-1)}Q) \oplus T^{(k)}Q$

$$\Phi^\alpha = 0 \quad \alpha = 1, \dots, m \quad (\text{constraints determining } \mathcal{M}) \quad (4.3)$$

$$\varphi_i^1 = 0 \quad i = 1, \dots, n. \quad (\text{primary relations}) \quad (4.4)$$

Therefore, the equations that define an integral curve of the solution X are given by

$$\begin{aligned} \frac{dq^{(r)i}}{dt} &= q^{(r+1)i}, \quad r = 0, \dots, k-1, \\ \frac{dp_i^{(0)}}{dt} &= \frac{\partial L}{\partial q^{(0)i}} - \lambda_\alpha \frac{\partial \Phi^\alpha}{\partial q^{(0)i}}, \\ \frac{dp_i^{(r)}}{dt} &= \frac{\partial L}{\partial q^{(r)i}} - \lambda_\alpha \frac{\partial \Phi^\alpha}{\partial q^{(r)i}} - p_i^{(r-1)}, \quad r = 1, \dots, k-1, \end{aligned} \quad (4.5)$$

and the constraint equations (4.3) and (4.4).

Differentiating with respect to time the equations φ_i^1 , substituting in (4.5) and proceeding further, we find the equations of motion for the higher-order variational problem analyzed in Section 3, i.e.

$$\sum_{r=0}^k (-1)^r \frac{d^r}{dt^r} \left(\frac{\partial L}{\partial q^{(r)i}} - \lambda_\alpha \frac{\partial \Phi^\alpha}{\partial q^{(r)i}} \right) = 0. \quad (4.6)$$

The solution of equation (4.1) on W_1 may not be tangent to W_1 . In such a case, we have to restrict W_1 to the submanifold W_2 where there exists at least a solution tangent to W_1 . Proceeding further, we obtain a sequence of submanifolds [16] (assuming that all the subsets generated by the algorithm are submanifolds)

$$\dots \hookrightarrow W_k \hookrightarrow \dots \hookrightarrow W_2 \hookrightarrow W_1 \hookrightarrow W_0.$$

Algebraically, these constraint submanifolds can be described as

$$W_i = \left\{ x \in T^* \left(T^{(k-1)}Q \right) \times_{T^{(k-1)}Q} \mathcal{M} \mid dH_{W_0}(x)(v) = 0 \quad \forall v \in (T_x W_{i-1})^\perp \right\} \quad i \geq 1, \quad (4.7)$$

where $(T_x W_{i-1})^\perp = \{ v \in T_x W_0 \mid \Omega_{W_0}(x)(u, v) = 0 \quad \forall u \in T_x W_{i-1} \}$.

If this constraint algorithm stabilizes, i.e., there exists a positive integer $k \in \mathbb{N}$ such that $W_{k+1} = W_k$ and $\dim W_k \geq 1$, then we will have at least a well defined solution X on $W_f = W_k$ such that

$$(i_X \Omega_{W_0} = dH_{W_0})|_{W_f}.$$

Now, denote by Ω_{W_1} , the pullback of presymplectic 2-form Ω_{W_0} to W_1 . In order to establish a necessary and sufficient condition for the symplecticity of the 2-form Ω_{W_1} , we define as in Section 3, the extended lagrangian

$$\mathcal{L} = L - \lambda_\alpha \Phi^\alpha.$$

Theorem 4.1. *For any choice of coordinates $(q^{(0)i}, q^{(1)i}, \dots, q^{(k-1)i}, p_i^{(0)}, \dots, p_i^{(k-1)}, q^{(k)i})$ in $T^*(T^{(k-1)}Q) \oplus T^{(k)}Q$, we have that (W_1, Ω_{W_1}) is a symplectic manifold if and only if*

$$\det \begin{pmatrix} \frac{\partial^2 \mathcal{L}}{\partial q^{(k)i} \partial q^{(k)j}} & -\frac{\partial \Phi^\alpha}{\partial q^{(k)i}} \\ \frac{\partial \Phi^\beta}{\partial q^{(k)j}} & \mathbf{0} \end{pmatrix} = \det \begin{pmatrix} \frac{\partial^2 L}{\partial q^{(k)i} \partial q^{(k)j}} - \lambda_\alpha \frac{\partial \Phi^\alpha}{\partial q^{(k)i} \partial q^{(k)j}} & -\frac{\partial \Phi^\alpha}{\partial q^{(k)i}} \\ \frac{\partial \Phi^\beta}{\partial q^{(k)j}} & \mathbf{0} \end{pmatrix} \neq 0 \quad (4.8)$$

(The proof follows the same lines that the one in Proposition 5.1).

Remark 4.2. Observe that if the determinant of the matrix in Theorem 4.1 is not zero, then we can apply the implicit function theorem to the equation of constraints $\varphi_i^1 = 0$ and $\Phi^\alpha = 0$, and we can express the Lagrange multipliers λ_α and higher-order velocities $q^{(k)i}$ in terms of coordinates $(q^{(0)i}, \dots, q^{(k-1)i}, p_i^{(0)}, \dots, p_i^{(k-1)})$, i.e.,

$$\begin{aligned} \lambda_\alpha &= \lambda_\alpha(q^{(0)}, q^{(1)}, \dots, q^{(k-1)}, p^{(0)}, \dots, p^{(k-1)}), \\ q^{(k)i} &= q^{(k)i}(q^{(0)}, q^{(1)}, \dots, q^{(k-1)}, p^{(0)}, \dots, p^{(k-1)}). \end{aligned}$$

Thus we can consider $(q^{(0)i}, q^{(1)i}, \dots, q^{(k-1)i}, p_i^{(0)}, \dots, p_i^{(k-1)})$ as local coordinates in W_1 . In this case,

$$\Omega_{W_1} = \sum_{r=0}^{k-1} dq^{(r)i} \wedge dp_i^{(r)}$$

which is obviously symplectic.

5. OPTIMAL CONTROL OF UNDERACTUATED MECHANICAL SYSTEMS

After introducing the geometry of higher-order Lagrangian system with constraints in the previous section, we may turn to the geometric framework for optimal control of underactuated mechanical systems. We recall that a Lagrangian control system is underactuated if the number of the control inputs is less than the dimension of the configuration space. We assume, in the sequel, that the considered systems are controllable [10].

Consider the class of underactuated Lagrangian control system (superarticulated mechanical system following the nomenclature by [2]) where the configuration space Q is the cartesian product of two differentiable manifolds, $Q = Q_1 \times Q_2$. Denote by $(q^A) = (q^a, q^\alpha)$, $1 \leq A \leq n$, local coordinates on Q where (q^a) , $1 \leq a \leq r$ and (q^α) , $r+1 \leq \alpha \leq n$, are local coordinates on Q_1 and Q_2 , respectively.

Given a Lagrangian $L : TQ \equiv TQ_1 \times TQ_2 \rightarrow \mathbb{R}$, we assume that the controlled external forces can be applied only to the coordinates (q^a) . Thus, the equations of motion are given by

$$\begin{aligned} \frac{d}{dt} \left(\frac{\partial L}{\partial \dot{q}^a} \right) - \frac{\partial L}{\partial q^a} &= u^a, \\ \frac{d}{dt} \left(\frac{\partial L}{\partial \dot{q}^\alpha} \right) - \frac{\partial L}{\partial q^\alpha} &= 0, \end{aligned} \tag{5.1}$$

where $a = 1, \dots, r$, and $\alpha = r+1, \dots, n$.

We study the optimal control problem that consists on finding a trajectory $(q^a(t), q^\alpha(t), u^a(t))$ of state variables and control inputs satisfying equations (5.1) from given initial and final conditions, $(q^a(t_0), q^\alpha(t_0), \dot{q}^a(t_0), \dot{q}^\alpha(t_0))$, $(q^a(t_f), q^\alpha(t_f), \dot{q}^a(t_f), \dot{q}^\alpha(t_f))$ respectively, minimizing the cost functional

$$\mathcal{A} = \int_{t_0}^{t_f} C(q^a, q^\alpha, \dot{q}^a, \dot{q}^\alpha, u^a) dt.$$

It is well know (see [7]) that this optimal control problem is equivalent to the following constrained variational problem.

Extremize

$$\tilde{\mathcal{A}} = \int_{t_0}^{t_f} \tilde{L}(q^a(t), q^\alpha(t), \dot{q}^a(t), \dot{q}^\alpha(t), \ddot{q}^a(t), \ddot{q}^\alpha(t)) dt$$

subject to the second order constraints given by

$$\Phi^\alpha(q^a, q^\alpha, \dot{q}^a, \dot{q}^\alpha, \ddot{q}^a, \ddot{q}^\alpha) = \frac{d}{dt} \left(\frac{\partial L}{\partial \dot{q}^\alpha} \right) - \frac{\partial L}{\partial q^\alpha} = 0,$$

and the boundary conditions, where $\tilde{L} : T^{(2)}Q \rightarrow \mathbb{R}$ is defined as

$$\tilde{L}(q^a, q^\alpha, \dot{q}^a, \dot{q}^\alpha, \ddot{q}^a, \ddot{q}^\alpha) = C \left(q^a, q^\alpha, \dot{q}^a, \dot{q}^\alpha, \frac{d}{dt} \left(\frac{\partial L}{\partial \dot{q}^\alpha} \right) - \frac{\partial L}{\partial q^\alpha} \right).$$

Now, according to the formulation given in Section 4, the dynamics of this second order constrained variational problem is determined by the solution of a presymplectic Hamiltonian system. In the following we repeat some of the constructions given in 4 but specialized to this particular setting, obtaining new insights for the optimal control problem under study.

If $\mathcal{M} \subset T^{(2)}Q$ is the submanifold given by annihilation of the functions Φ^α , we will see how to define local coordinates on $\mathcal{M}$.

From the constraint equations we have

$$\frac{d}{dt} \left(\frac{\partial L}{\partial \dot{q}^\alpha} \right) - \frac{\partial L}{\partial q^\alpha} = 0 \iff \frac{\partial^2 L}{\partial \dot{q}^\beta \partial \dot{q}^\alpha} \ddot{q}^\beta = F_\alpha(q^i, \dot{q}^i, \ddot{q}^a).$$

Let us assume that the matrix $(W_{\alpha\beta}) = \left(\frac{\partial^2 L}{\partial \dot{q}^\alpha \partial \dot{q}^\beta} \right)$ is non-singular and denote by $(W^{\alpha\beta})$ its inverse. Thus,

$$\ddot{q}^\alpha = W^{\alpha\beta} F_\beta(q^i, \dot{q}^i, \ddot{q}^a) = G^\alpha(q^i, \dot{q}^i, \ddot{q}^a).$$

Therefore, we can consider $(q^i, \dot{q}^i, \ddot{q}^a)$ as a system of local coordinates on $\mathcal{M}$. The canonical inclusion $i_{\mathcal{M}} : \mathcal{M} \hookrightarrow TTQ$ can be written as

$$\begin{array}{ccc} \mathcal{M} & \xrightarrow{i_{\mathcal{M}}} & TTQ \\ (q^i, \dot{q}^i, \ddot{q}^a) & \mapsto & (q^i, \dot{q}^i, \ddot{q}^a, G^\alpha(q^i, \dot{q}^i, \ddot{q}^a)) . \end{array}$$

Define the restricted lagrangian $\tilde{L}|_{\mathcal{M}} : \mathcal{M} \rightarrow \mathbb{R}$.

FIGURE 1. Second order Skinner and Rusk formalism

We will consider $W_0 = T^*(TQ) \times_{TQ} \mathcal{M}$ whose coordinates are $(q^i, \dot{q}^i; p_i^0, p_i^1, \ddot{q}^a)$.

Let us define the 2-form $\Omega_{W_0} = \pi_1^*(\omega_{TQ})$ on W_0 and $H_{W_0}(\alpha_x, v_x) = \langle \alpha_x, i_{\mathcal{M}}(v_x) \rangle - \tilde{L}_{\mathcal{M}}(v_x)$ where $x \in TQ$, $v_x \in \mathcal{M}_x = ((\tau_Q^{(1,2)})|_{\mathcal{M}})^{-1}(x)$ and $\alpha_x \in T_x^*TQ$. In local coordinates,

$$\begin{aligned} \Omega_{W_0} &= dq^i \wedge dp_i^0 + d\dot{q}^i \wedge dp_i^1, \\ H_{W_0} &= p_i^0 \dot{q}^i + p_a^1 \ddot{q}^a + p_\alpha^1 G^\alpha(q^i, \dot{q}^i, \ddot{q}^a) - \tilde{L}_{\mathcal{M}}(q^i, \dot{q}^i, \ddot{q}^a). \end{aligned}$$

The dynamics of this variational constrained problem is determined by the solution of the equation

$$i_X \Omega_{W_0} = dH_{W_0}. \quad (5.2)$$

It is clear that Ω_{W_0} is a presymplectic form on W_0 and locally

$$\ker \Omega_{W_0} = \text{span} \left\langle \frac{\partial}{\partial \ddot{q}^a} \right\rangle.$$

Following the Gotay-Nester-Hinds algorithm we obtain the primary constraints

$$dH_{W_0} \left(\frac{\partial}{\partial \ddot{q}^a} \right) = 0.$$

That is,

$$\varphi_a^1 = \frac{\partial H_{W_0}}{\partial \ddot{q}^a} = p_a^1 + p_\alpha^1 \frac{\partial G^\alpha}{\partial \ddot{q}^a} - \frac{\partial \tilde{L}_{\mathcal{M}}}{\partial \ddot{q}^a} = 0.$$

These new constraints $\varphi_a^1 = 0$ give rise to a submanifold W_1 of dimension $4n$ with local coordinates $(q^i, \dot{q}^i, \ddot{q}^a, p_i^0, p_\alpha^1)$.

Consider a solution curve $(q^i(t), \dot{q}^i(t), \ddot{q}^a(t), p_i^0(t), p_i^1(t))$ of Equation (5.2). Then, this curve satisfies the following system of differential equations

$$\frac{dq^i}{dt} = \dot{q}^i, \quad \frac{d^2q^a}{dt^2} = \ddot{q}^a, \quad (5.3)$$

$$\frac{d^2q^\alpha}{dt^2} = G^\alpha(q^i, \frac{dq^i}{dt}, \frac{d^2q^a}{dt^2}), \quad (5.4)$$

$$\frac{dp_i^0}{dt} = -p_\alpha^1 \frac{\partial G^\alpha}{\partial \dot{q}^i} + \frac{\partial \tilde{L}_M}{\partial \dot{q}^i}, \quad (5.5)$$

$$\frac{dp_i^1}{dt} = -p_i^0 - p_\alpha^1 \frac{\partial G^\alpha}{\partial \dot{q}^i} + \frac{\partial \tilde{L}_M}{\partial \dot{q}^i}, \quad (5.6)$$

$$p_a^1 = -p_\alpha^1 \frac{\partial G^\alpha}{\partial \dot{q}^a} + \frac{\partial \tilde{L}_M}{\partial \dot{q}^a}. \quad (5.7)$$

From Equations (5.6) and (5.7) we deduce

$$\frac{d}{dt} \left(\frac{\partial \tilde{L}_M}{\partial \dot{q}^a} - p_\alpha^1 \frac{\partial G^\alpha}{\partial \dot{q}^a} \right) = -p_a^0 - p_\alpha^1 \frac{\partial G^\alpha}{\partial \dot{q}^a} + \frac{\partial \tilde{L}_M}{\partial \dot{q}^a}.$$

Differentiating with respect to time, replacing in the previous equality and using (5.5) we obtain the following system of 4-order differential equations

$$\frac{d^2}{dt^2} \left(\frac{\partial \tilde{L}_M}{\partial \dot{q}^a} - p_\alpha^1 \frac{\partial G^\alpha}{\partial \dot{q}^a} \right) - \frac{d}{dt} \left(\frac{\partial \tilde{L}_M}{\partial \dot{q}^a} - p_\alpha^1 \frac{\partial G^\alpha}{\partial \dot{q}^a} \right) + \frac{\partial \tilde{L}_M}{\partial q^a} - p_\alpha^1 \frac{\partial G^\alpha}{\partial q^a} = 0. \quad (5.8)$$

Also, using (5.5) and (5.6) we deduce

$$\frac{d^2 p_\alpha^1}{dt^2} = \frac{d}{dt} \left(\frac{\partial \tilde{L}_M}{\partial \dot{q}^\alpha} - p_\beta^1 \frac{\partial G^\beta}{\partial \dot{q}^\alpha} \right) - \left(\frac{\partial \tilde{L}_M}{\partial q^\alpha} - p_\beta^1 \frac{\partial G^\beta}{\partial q^\alpha} \right). \quad (5.9)$$

If we solve the implicit system of differential equations given by (5.8) and (5.9) then from Equations (5.6) and (5.7) we deduce that the values of p_a^0 and p_α^0 are

$$p_a^0 = \frac{\partial \tilde{L}_M}{\partial \dot{q}^a} - p_\alpha^1 \frac{\partial G^\alpha}{\partial \dot{q}^a} - \frac{d}{dt} \left(\frac{\partial \tilde{L}_M}{\partial \dot{q}^a} - p_\alpha^1 \frac{\partial G^\alpha}{\partial \dot{q}^a} \right), \quad (5.10)$$

$$p_\alpha^0 = \frac{\partial \tilde{L}_M}{\partial \dot{q}^\alpha} - p_\beta^1 \frac{\partial G^\beta}{\partial \dot{q}^\alpha} - \frac{dp_\alpha^1}{dt}. \quad (5.11)$$

Since, from our initial problem, we are only interested in the values $q^A(t)$, it is uniquely necessary to solve the coupled system of implicit differential equations given by (5.8), (5.9) and (5.4) without explicitly calculate the values $p_a^0(t)$.

Now, we are interested in the geometric properties of the dynamics. First, consider the submanifold W_1 of W_0 determined by

$$W_1 = \{x \in T^*TQ \times_{TQ} M \mid dH_{W_0}(x)(V) = 0 \ \forall \ V \in \ker \Omega(x)\}$$

and the 2-form $\Omega_{W_1} = i_{W_1}^* \Omega_{W_0}$, where $i_{W_1} : W_1 \hookrightarrow W_0$ denotes the canonical inclusion. Locally, W_1 is determined by the vanishing of the constraint equations

$$\varphi_a^1 = p_a^1 + p_\alpha^1 \frac{\partial G^\alpha}{\partial \dot{q}^a} - \frac{\partial \tilde{L}_M}{\partial \dot{q}^a} = 0.$$

Therefore, we can consider local coordinates $(q^i, \dot{q}^i, \ddot{q}^a, p_i^0, p_\alpha^1)$ on W_1 .

Proposition 5.1. *(W_1, Ω_{W_1}) is symplectic if and only if for any choice of local coordinates $(q^i, \dot{q}^i, \ddot{q}^a, p_i^0, p_\alpha^1)$ on W_0 ,*

$$\det(\mathcal{R}_{ab}) = \det \left(\frac{\partial^2 \tilde{L}_M}{\partial \ddot{q}^a \partial \ddot{q}^b} - p_\alpha^1 \frac{\partial^2 G^\alpha}{\partial \ddot{q}^a \partial \ddot{q}^b} \right) \neq 0 \text{ along } W_1. \quad (5.12)$$

(n-r) × (n-r)

Proof:

Let us recall that Ω_{W_1} is symplectic of and only if $T_x W_1 \cap (T_x W_1)^\perp = 0 \quad \forall x \in W_1$, where

$$(T_x W_1)^\perp = \{v \in T_x(T^*TQ) \times_{TQ} \mathcal{M} \mid \Omega_{W_0}(x)(v, w) = 0, \text{ for all } w \in T_x W_1\}.$$

Suppose that (W_1, Ω_{W_1}) is symplectic and that

$$\lambda^a \mathcal{R}_{ab}(x) = 0 \text{ for some } \lambda^a \in \mathbb{R} \text{ and } x \in W_1.$$

Hence

$$\lambda^b \mathcal{R}_{ab}(x) = \lambda^b d\varphi_a(x) \left(\frac{\partial}{\partial \dot{q}^b} \Big|_x \right) = 0.$$

Therefore, $\lambda^b \frac{\partial}{\partial \dot{q}^b} \Big|_x \in T_x W_1$ but it is also in $T_x W_1^\perp$. This implies that $\lambda_b = 0$ for all b and that the matrix $(\mathcal{R}_{ab})$ is regular.

Now, suppose that the matrix $(\mathcal{R}_{ab})$ is regular. Since

$$\mathcal{R}_{ab}(x) = d\varphi_a(x) \left(\frac{\partial}{\partial \dot{q}^b} \Big|_x \right),$$

then, $\frac{\partial}{\partial \dot{q}^b} \Big|_x \notin T_x W_1$ and, in consequence,

$$T_x W_1 \oplus \text{span} \left\{ \frac{\partial}{\partial \dot{q}^b} \Big|_x \right\} = T_x W_0.$$

Now, let $Z \in T_x W_1 \cap (T_x W_1)^\perp$ with $x \in W_1$. It follows that

$$0 = i_Z \Omega_{W_0}(x) \left(\frac{\partial}{\partial \dot{q}^a} \Big|_x \right), \text{ for all } a \text{ and } i_Z \Omega_{W_0}(x)(\bar{Z}) = 0, \text{ for all } \bar{Z} \in T_x W_1.$$

Then, $Z \in \ker \Omega_{W_0}(x)$. This implies that

$$Z = \lambda_b \frac{\partial}{\partial \dot{q}^b} \Big|_x$$

Since $Z \in T_x W_1$ then

$$0 = d\varphi_a(x)(Z) = d\varphi_a(x) \left(\lambda_b \frac{\partial}{\partial \dot{q}^b} \Big|_x \right) = \lambda_b \mathcal{R}_{ab}$$

and, consequently, $\lambda_b = 0$, for all b , and $Z = 0$. ■

In the case where the matrix (5.12) is regular then the equations (5.8), (5.9) and (5.4) can be written as an explicit system of differential equations of the form

$$\frac{d^4 q^a}{dt^4} = \Gamma^a \left(q^i, \frac{dq^i}{dt}, \frac{d^2 q^a}{dt^2}, \frac{d^3 q^a}{dt^3}, p_\alpha^1, \frac{dp_\alpha^1}{dt} \right) \quad (5.13)$$

$$\frac{d^2 q^\alpha}{dt^2} = G^\alpha \left(q^i, \frac{dq^i}{dt}, \frac{d^2 q^a}{dt^2} \right) \quad (5.14)$$

$$\frac{d^2 p_\alpha^1}{dt^2} = \frac{d}{dt} \left(\frac{\partial \tilde{L}_\mathcal{M}}{\partial \dot{q}^\alpha} - p_\beta^1 \frac{\partial G^\beta}{\partial \dot{q}^\alpha} \right) - \left(\frac{\partial \tilde{L}_\mathcal{M}}{\partial q^\alpha} - p_\beta^1 \frac{\partial G^\beta}{\partial q^\alpha} \right). \quad (5.15)$$

Remark 5.2. Now, we will analyze an alternative characterization of the condition (5.12) and its relationship with the matrix condition that appears in Theorem 4.1. Using the chain rule

$$\begin{aligned} \frac{\partial \tilde{L}_\mathcal{M}}{\partial \ddot{q}^a} &= \frac{\partial \tilde{L}}{\partial \ddot{q}^a} + \frac{\partial \tilde{L}}{\partial \ddot{q}^a} \frac{\partial G^\alpha}{\partial \ddot{q}^a} \\ \frac{\partial^2 \tilde{L}_\mathcal{M}}{\partial \ddot{q}^a \partial \ddot{q}^b} &= \frac{\partial^2 \tilde{L}}{\partial \ddot{q}^a \partial \ddot{q}^b} + \frac{\partial^2 \tilde{L}}{\partial \ddot{q}^a \partial \ddot{q}^\beta} \frac{\partial G^\beta}{\partial \ddot{q}^b} + \frac{\partial^2 \tilde{L}}{\partial \ddot{q}^\alpha \partial \ddot{q}^b} \frac{\partial G^\alpha}{\partial \ddot{q}^a} + \frac{\partial^2 \tilde{L}}{\partial \ddot{q}^\alpha \partial \ddot{q}^\beta} \frac{\partial G^\alpha}{\partial \ddot{q}^a} \frac{\partial G^\beta}{\partial \ddot{q}^b} + \frac{\partial^2 \tilde{L}}{\partial \ddot{q}^\alpha \partial \ddot{q}^a} \frac{\partial^2 G^\alpha}{\partial \ddot{q}^a \partial \ddot{q}^b}. \end{aligned}$$

Define $W_{ij} = \left(\frac{\partial^2 \tilde{L}}{\partial \ddot{q}^i \partial \ddot{q}^j} \right)$, where $\Phi^\alpha = \ddot{q}^\alpha - G^\alpha$. Then we can write (5.12) as

$$\mathcal{R}_{ab} = W_{ab} - W_{a\beta} \frac{\partial \Phi^\beta}{\partial \ddot{q}^b} - W_{\alpha b} \frac{\partial \Phi^\alpha}{\partial \ddot{q}^a} + W_{\alpha\beta} \frac{\partial \Phi^\alpha}{\partial \ddot{q}^a} \frac{\partial \Phi^\beta}{\partial \ddot{q}^b} + \left(p_\alpha^1 - \frac{\partial \tilde{L}}{\partial \dot{q}^\alpha} \right) \frac{\partial^2 \Phi^\alpha}{\partial \ddot{q}^a \partial \ddot{q}^b}.$$

Consider now the extended lagrangian $\mathcal{L} = \tilde{L} - \lambda_\alpha \Phi^\alpha$ where $\lambda_\alpha = \frac{\partial \tilde{L}}{\partial \dot{q}^\alpha} - p_\alpha^1$.

Then, the matrix $(\overline{W}_{ij}) = \left(\frac{\partial^2 \mathcal{L}}{\partial \ddot{q}^i \partial \ddot{q}^j} \right)$ is equal, along W_1 , to

$$\overline{W}_{ij} = \begin{pmatrix} \overline{W}_{ab} & W_{a\beta} \\ W_{\alpha b} & W_{\alpha\beta} \end{pmatrix} \quad (5.16)$$

where $\overline{W}_{ab} = \frac{\partial^2 \tilde{L}}{\partial \ddot{q}^a \partial \ddot{q}^b} - \lambda_\alpha \frac{\partial^2 \Phi^\alpha}{\partial \ddot{q}^a \partial \ddot{q}^b}$.

It is easy to see that the elements of the matrix (5.12) are given by

$$\mathcal{R}_{ab} = \overline{W}_{ab} - \overline{W}_{a\beta} \frac{\partial \Phi^\beta}{\partial \ddot{q}^b} - \overline{W}_{\alpha b} \frac{\partial \Phi^\alpha}{\partial \ddot{q}^a} + \overline{W}_{\alpha\beta} \frac{\partial \Phi^\alpha}{\partial \ddot{q}^a} \frac{\partial \Phi^\beta}{\partial \ddot{q}^b}. \quad (5.17)$$

Now, using elemental linear algebra it is easy to show that matrix (5.17) is regular if and only if the matrix of elements (5.16) is regular.

◇

Example 5.3. The Cart-Pole System (see [7] and references therein). A Cart-Pole System consists of a cart and an inverted pendulum on it. The coordinate x denotes the position of the cart on the x -axis and θ denotes the angle of the pendulum with the upright vertical. The configuration space is $Q = \mathbb{R} \times \mathbb{S}^1$.

First, we describe the Lagrangian function describing this system. The inertia matrix of the cart-pole system is given by

$$\begin{aligned} m_{11} &= M + m \\ m_{12}(q_2) &= m_{12}(q_2) = ml \cos(\theta) \\ m_{22} &= ml^2 \end{aligned}$$

where M is the mass of the cart and m, l are the mass, and length of the center of mass of pendulum, respectively. The potential energy of the cart-pole system is $V(\theta) = mgl \cos(\theta)$.

The Lagrangian of the system (kinetic energy minus potential energy) is given by

$$L(q, \dot{q}) = L(x, \theta, \dot{x}, \dot{\theta}) = \frac{1}{2}M\dot{x}^2 + \frac{1}{2}m(\dot{x}^2 + 2\dot{x}l\dot{\theta}\cos\theta + l^2\dot{\theta}^2) - mgl\cos\theta - mg\tilde{h},$$

where $\tilde{h}$ is the car height.

The controller can apply a force F , the control input, parallel to the track remaining the joint angle θ unactuated. Therefore, the equations of motion of the controlled system are

$$\begin{aligned} (M + m)\ddot{x} - ml\dot{\theta}^2\sin\theta + ml\ddot{\theta}\cos\theta &= u \\ \ddot{x}\cos\theta + l\ddot{\theta} - g\sin\theta &= 0 \end{aligned}$$

Now we look for trajectories $(x(t), \theta(t)), u(t)$ on the state variables and the controls inputs with initial and final conditions, $(x(0), \theta(0), \dot{x}(0), \dot{\theta}(0))$, $(x(T), \theta(T), \dot{x}(T), \dot{\theta}(T))$ respectively, and minimizing the cost functional

$$\mathcal{A} = \frac{1}{2} \int_0^T u^2 dt.$$

Following our formalism this optimal control problem is equivalent to the constrained second-order variational problem determined by

$$\tilde{\mathcal{A}} = \int_0^T \tilde{L}(x, \theta, \dot{x}, \dot{\theta}, \ddot{x}, \ddot{\theta})$$

and the second-order constraint

$$\Phi(x, \theta, \dot{x}, \dot{\theta}, \ddot{x}, \ddot{\theta}) = \ddot{x}\cos\theta + l\ddot{\theta} - g\sin\theta = 0,$$

where

$$\tilde{L}(x, \theta, \dot{x}, \dot{\theta}, \ddot{x}, \ddot{\theta}) = \frac{1}{2} \left(\frac{d}{dt} \left(\frac{\partial L}{\partial \dot{x}} \right) - \frac{\partial L}{\partial x} \right)^2 = \frac{1}{2} \left[(M + m)\ddot{x} - ml\dot{\theta}^2\sin\theta + ml\ddot{\theta}\cos\theta \right]^2.$$

We rewrite the second-order constraint as

$$\ddot{\theta} = \frac{g\sin\theta - \ddot{x}\cos\theta}{l}.$$

Thus, the submanifold $\mathcal{M}$ of $T^{(2)}(\mathbb{R} \times \mathbb{S}^1)$ is given by

$$\mathcal{M} = \left\{ (x, \theta, \dot{x}, \dot{\theta}, \ddot{x}, \ddot{\theta}) \mid \ddot{x}\cos\theta + l\ddot{\theta} - g\sin\theta = 0 \right\}.$$

Let us consider the submanifold $W_0 = T^*(T(\mathbb{R} \times \mathbb{S}^1)) \times_{T(\mathbb{R} \times \mathbb{S}^1)} \mathcal{M}$ with induced coordinates $(x, \theta, \dot{x}, \dot{\theta}; p_x^0, p_\theta^0, p_x^1, p_\theta^1, \ddot{x})$.

Now, we consider the restriction of $\tilde{L}$ to $\mathcal{M}$ given by

$$\begin{aligned} \tilde{L}|_{\mathcal{M}} &= \frac{1}{2} \left[(M + m)\ddot{x} - ml\sin\theta\dot{\theta}^2 + ml\cos\theta \left(\frac{g\sin\theta - \ddot{x}\cos\theta}{l} \right) \right]^2 \\ &= \frac{1}{2} \left[(M + m)\ddot{x} - ml\dot{\theta}^2\sin\theta + mg\cos\theta\sin\theta - m\ddot{x}\cos^2\theta \right]^2. \end{aligned}$$

For simplicity, denote by

$$G^\theta = \frac{g\sin\theta - \ddot{x}\cos\theta}{l}.$$

Now, the presymplectic 2-form Ω_{W_0} , the Hamiltonian H_{W_0} and the primary constraint φ_x^1 are, respectively

$$\begin{aligned}\Omega_{W_0} &= dx \wedge dp_x^0 + d\theta \wedge dp_\theta^0 + d\dot{x} \wedge dp_x^1 + d\dot{\theta} \wedge dp_\theta^1, \\ H_{W_0} &= p_x^0 \dot{x} + p_\theta^0 \dot{\theta} + p_x^1 \ddot{x} + p_\theta^1 \left[\frac{g \sin \theta - \ddot{x} \cos \theta}{l} \right] \\ &\quad - \frac{1}{2} \left[(M+m) \ddot{x} - ml \dot{\theta}^2 \sin \theta + mg \cos \theta \sin \theta - m \ddot{x} \cos^2 \theta \right]^2, \\ \varphi_x^1 &= \frac{\partial \tilde{H}}{\partial \ddot{x}} = p_x^1 + p_\theta^1 \frac{\partial G^\theta}{\partial \ddot{x}} - \frac{\partial \tilde{L}_M}{\partial \ddot{x}} = 0,\end{aligned}$$

i.e.,

$$p_x^1 = -p_\theta^1 \frac{\partial G^\theta}{\partial \ddot{x}} + \frac{\partial \tilde{L}_M}{\partial \ddot{x}}.$$

This constraint determines the submanifold W_1 . Applying Proposition 5.1 we deduce that the 2-form Ω_{W_1} , restriction of Ω_{W_0} to W_1 , is symplectic since

$$\frac{\partial^2 \tilde{L}_M}{\partial \ddot{x}^2} - p_\theta^1 \frac{\partial^2 G^\theta}{\partial \ddot{x}^2} = [(M+m) - m \cos^2 \theta]^2 \neq 0.$$

Therefore, the algorithm stabilizes at the first constraint submanifold W_1 . Moreover, there exists a unique solution of the dynamics, the vector field $X \in \mathfrak{X}(W_1)$ which satisfies $i_X \Omega_{W_1} = dH_{W_1}$. In consequence, we have a unique control input which extremizes (minimizes) the objective function $\mathcal{A}$ and then the force exerted to the car is the minimum possible. If we take the flow $F_t : W_1 \rightarrow W_1$ of the vector field X then we have that $F_t^* \Omega_{W_1} = \Omega_{W_1}$. Obviously, the hamiltonian function

$$\begin{aligned}\tilde{H}|_{W_1} &= p_x^0 \dot{x} + p_\theta^0 \dot{\theta} + \left[-p_\theta^1 \frac{\partial G^\theta}{\partial \ddot{x}} + \frac{\partial \tilde{L}_N}{\partial \ddot{x}} \right] \ddot{x} + p_\theta^1 \left[\frac{g \sin \theta - \ddot{x} \cos \theta}{l} \right] - \\ &\quad \frac{1}{2} \left[(M+m) \ddot{x} - ml \sin \theta \dot{\theta}^2 + mg \cos \theta \sin \theta - m \ddot{x} \cos^2 \theta \right]^2\end{aligned}$$

is preserved by the solution of the optimal control problem, that is $\tilde{H}|_{W_1} \circ F_t = \tilde{H}|_{W_1}$. Both properties, symplecticity and preservation of energy, are important geometric invariants. In next section, we will construct, using discrete variational calculus, numerical integrators which inherit some of the geometric properties of the optimal control problem (symplecticity, momentum preservation and, in consequence, a very good energy behavior).

6. GEOMETRIC DISCRETIZATION OF OPTIMAL CONTROL PROBLEMS FOR UNDERACTUATED MECHANICAL SYSTEMS

6.1. Discrete vakonomic mechanics. In this section we discuss some ideas from discrete mechanics for vakonomic systems (see [4]). The main idea is to use discrete variational calculus. In the case of vakonomic systems, the principle seeks to find a discrete curve which is a critical point of the discrete action sum subject to some constraint functions. The discrete curves are sequences of points that approximate curves on Q .

The discretizing procedure of a given continuous vakonomic system, determined by a Lagrangian function $L : TQ \rightarrow \mathbb{R}$ and a constraint submanifold $\mathcal{M}$ of TQ , starts first substituting the velocity phase space TQ by the cartesian product of two copies of Q , $Q \times Q$. Secondly, we discretize the continuous lagrangian and the constraint submanifold to a discrete lagrangian function $L_d : Q \times Q \rightarrow \mathbb{R}$ and a constraint submanifold $\mathcal{M}_d$ of $Q \times Q$ determined by the vanishing of m -independent constraints functions $\Phi_d^\alpha : Q \times Q \rightarrow \mathbb{R}$.

Given q_0 and q_N in Q , for some (also fixed) integer N , we consider the space of sequences $(q_0, q_1, \dots, q_N)$ (the discrete paths joining q_0 to q_N). We form the discrete action sum

$$\mathcal{A}_d(q_0, q_1, \dots, q_N) = \sum_{k=0}^{N-1} L_d(q_k, q_{k+1})$$

over discrete paths satisfying the discrete constraints equations, that is $\Phi_d^\alpha(q_k, q_{k+1}) = 0$, with $k = 0, \dots, N-1$. We compute the critical point of this action sum subjected to the constraint equations; that is,

$$\begin{cases} \min \mathcal{A}_d(q_0, q_1, \dots, q_N) & \text{with } q_0 \text{ and } q_N \text{ fixed} \\ \text{subject to } \Phi_d^\alpha(q_k, q_{k+1}) = 0, & 1 \leq \alpha \leq m \text{ and } 0 \leq k \leq N-1. \end{cases} \quad (6.1)$$

Observe that system is subjected to Nm constraint functions.

We define the **augmented Lagrangian** $\mathcal{L}_d : Q \times Q \times \mathbb{R}^m \rightarrow \mathbb{R}$ by

$$\mathcal{L}_d(x, y, \lambda) = L_d(x, y) + \lambda_\alpha \Phi_d^\alpha(x, y).$$

This Lagrangian $\mathcal{L}_d$ gives rise to the following unconstrained discrete variational problem

$$\begin{cases} \min \bar{\mathcal{A}}_d(q_0, q_1, \dots, q_N, \lambda^0, \lambda^1, \dots, \lambda^{N-1}) & \text{with } q_0 \text{ and } q_N \text{ fixed} \\ q_k \in Q, \quad \lambda_k \in \mathbb{R}^m \quad k = 0, \dots, N-1, & q_N \in Q, \end{cases} \quad (6.2)$$

where

$$\begin{aligned} \bar{\mathcal{A}}_d(q_0, q_1, \dots, q_N, \lambda^0, \lambda^1, \dots, \lambda^{N-1}) &= \sum_{k=0}^{N-1} \mathcal{L}_d(q_k, q_{k+1}, \lambda^k) \\ &= \sum_{k=0}^{N-1} [L_d(q_k, q_{k+1}) + \lambda_\alpha^k \Phi_d^\alpha(q_k, q_{k+1})], \end{aligned}$$

where λ^k is a m -vector with components λ_α^k with $1 \leq \alpha \leq m$.

From the classical lagrangian multiplier theorem, we have that the regular extremals of Problem (6.1) are the same than in Problem (6.2). Therefore, applying standard discrete variational calculus we deduce that the solutions of problem (6.1) verify the following set of difference equations

$$\begin{cases} D_1 L_d(q_k, q_{k+1}) + D_2 L_d(q_{k-1}, q_k) + \lambda_\alpha^k D_1 \Phi_d^\alpha(q_k, q_{k+1}) + \lambda_\alpha^{k-1} D_2 \Phi_d^\alpha(q_{k-1}, q_k) = 0, & 1 \leq k \leq N-1, \\ \Phi_d^\alpha(q_k, q_{k+1}) = 0, & 1 \leq \alpha \leq m, \text{ and } 0 \leq k \leq N-1 \end{cases}$$

where $D_1 L_d$ and $D_2 L_d$ denote the derivatives of the discrete lagrangian L_d respect to the first and the second argument, respectively.

For all function $F \in C^\infty(Q \times Q)$, we denote by $D_{12}F$ the $n \times n$ -matrix $\left(\frac{\partial^2 F}{\partial x^i \partial y^j} \right)$ (partial derivatives with respect to the first and second variables). Then, if the matrix

$$\begin{pmatrix} D_{12}L_d + \lambda_\alpha D_{12}\Phi_d^\alpha & \frac{\partial \Phi_d^\alpha}{\partial x} \\ \left(\frac{\partial \Phi_d^\alpha}{\partial y} \right)^T & \mathbf{0}_{m \times m} \end{pmatrix}_{(n+m) \times (n+m)}$$

is regular along $\mathcal{M}_d \times \mathbb{R}^m$, then, by a direct application of the implicit function theorem, we deduce that there exists a unique map

$$\begin{aligned} \Upsilon_d : \mathcal{M}_d \times \mathbb{R}^m &\longrightarrow \mathcal{M}_d \times \mathbb{R}^m \\ (x, y, \lambda) &\longmapsto (y, v, \Lambda), \end{aligned}$$

such that for all solutions $(q_0, q_1, \dots, q_N, \lambda^0, \lambda^1, \dots, \lambda^{N-1})$ of the equation (6.1) we have that

$$\Upsilon_d(q_{k-1}, q_k, \lambda^{k-1}) = (q_k, q_{k+1}, \lambda^k).$$

The application Υ_d will be called the **discrete flow** of the vakonomic problem.

In [6], it is shown that the discrete flow Υ_d preserves a symplectic form naturally defined on $\mathcal{M}_d \times \mathbb{R}^m$ and it is momentum preserving if the discrete Lagrangian L_d and the constraint submanifold $\mathcal{M}_d$ are invariant under the action of a Lie group of symmetries.

6.2. Discrete second-order vakonomic mechanics. In this subsection, we study discrete second-order mechanical systems with constraints (see [6]) bearing in mind the discretization of optimal control problems for underactuated mechanical systems.

A natural discrete space substituting the second-order tangent bundle $T^{(2)}Q$ is $Q \times Q \times Q$ and therefore a discrete vakonomic system is determined by a discrete lagrangian $\tilde{L}_d : Q \times Q \times Q \rightarrow \mathbb{R}$ and a constraint submanifold $\mathcal{M}_d$ is locally determined by the vanishing of m -constraint functions $\Phi_d^\alpha : Q \times Q \times Q \rightarrow \mathbb{R}$.

Given a discrete lagrangian $\tilde{L}_d : Q \times Q \times Q \rightarrow \mathbb{R}$ we define the **discrete action** $\mathcal{A}_d : Q^{N+1} \rightarrow \mathbb{R}$ by

$$\mathcal{A}_d(q_0, \dots, q_N) = \sum_{k=0}^{N-2} \tilde{L}_d(q_k, q_{k+1}, q_{k+2}).$$

Adding the constraints, we have the following discrete constrained variational problem

$$\begin{cases} \min \mathcal{A}_d(q_0, q_1, \dots, q_N), & \text{with } q_0, q_1 \text{ and } q_{N-1}, q_N \text{ fixed} \\ \text{subject to } \Phi_d^\alpha(q_k, q_{k+1}, q_{k+2}) = 0, & \text{with } 1 \leq \alpha \leq m, 0 \leq k \leq N-1. \end{cases} \quad (6.3)$$

As in the previous section we define the augmented lagrangian $\mathcal{L}_d : Q \times Q \times Q \times \mathbb{R}^m \rightarrow \mathbb{R}$ given by

$$\mathcal{L}_d(q_k, q_{k+1}, q_{k+2}, \lambda^k) = \tilde{L}_d(q_k, q_{k+1}, q_{k+2}) + \lambda_\alpha^k \Phi_d^\alpha(q_k, q_{k+1}, q_{k+2})$$

with $q_k \in Q$; $\lambda^k = (\lambda_1^k, \dots, \lambda_m^k) \in \mathbb{R}^m$, $0 \leq k \leq N-2$. Hence, as in the previous section, Problem (6.3) is equivalent to the following (singular) unconstrained problem for $\mathcal{L}_d$

$$\begin{cases} \min \bar{\mathcal{A}}_d(q_0, q_1, \dots, q_N, \lambda^0, \lambda^1, \dots, \lambda^{N-1}) & \text{with } q_0, q_1 \text{ and } q_{N-1}, q_N \text{ fixed} \\ (q_k, q_{k+1}, q_{k+2}) \in Q \times Q \times Q, & \lambda_k \in \mathbb{R}^m, \quad k = 0, \dots, N-2, \end{cases} \quad (6.4)$$

where

$$\begin{aligned} \bar{\mathcal{A}}_d(q_0, q_1, \dots, q_N, \lambda^0, \lambda^1, \dots, \lambda^{N-2}) &= \sum_{k=0}^{N-2} \mathcal{L}_d(q_k, q_{k+1}, q_{k+2}, \lambda^k) \\ &= \sum_{k=0}^{N-2} \left[\tilde{L}_d(q_k, q_{k+1}, q_{k+2}) + \lambda_\alpha^k \Phi_d^\alpha(q_k, q_{k+1}, q_{k+2}) \right] \end{aligned}$$

and λ^k is a m -vector with components λ_α^k , $1 \leq \alpha \leq m$.

Hence, the extremality conditions are

$$\begin{aligned} 0 &= D_3 \tilde{L}_d(q_{k-2}, q_{k-1}, q_k) + D_2 \tilde{L}_d(q_{k-1}, q_k, q_{k+1}) \\ &\quad + D_1 \tilde{L}_d(q_k, q_{k+1}, q_{k+2}) + \lambda_\alpha^{k-2} D_3 \Phi_d^\alpha(q_{k-2}, q_{k-1}, q_k) \\ &\quad + \lambda_\alpha^{k-1} D_2 \Phi_d^\alpha(q_{k-1}, q_k, q_{k+1}) + \lambda_\alpha^k D_1 \Phi_d^\alpha(q_k, q_{k+1}, q_{k+2}), \\ 0 &= \Phi_d^\alpha(q_{k-2}, q_{k-1}, q_k) \\ 0 &= \Phi_d^\alpha(q_{k-1}, q_k, q_{k+1}) \\ 0 &= \Phi_d^\alpha(q_k, q_{k+1}, q_{k+2}). \end{aligned}$$

where $2 \leq k \leq N-2$.

If the matrix

$$\det \begin{pmatrix} D_{13} \tilde{L}_d(x, y, z) + \lambda_\alpha D_{13} \Phi_d^\alpha(x, y, z) & D_3 \Phi_d^\alpha(x, y, z) \\ D_1 \Phi_d^\alpha(x, y, z) & 0 \end{pmatrix} \neq 0, \quad (6.5)$$

is regular for all $(x, y, z) \in \mathcal{M}_d = \{(x, y, z) \in Q \times Q \times Q \mid \Phi_d^\alpha(x, y, z) = 0\}$ and $\lambda_\alpha \in \mathbb{R}$, $1 \leq \alpha \leq m$. Assuming this regularity assumption and by a direct application of the implicit function theorem, we deduce that there exists a unique application

$$\Upsilon_d : \begin{array}{ccc} \overline{\mathcal{M}}_d \times \mathbb{R}^{2m} & \longrightarrow & \overline{\mathcal{M}}_d \times \mathbb{R}^{2m} \\ (q_0, q_1, q_2, q_3, \lambda_\alpha^0, \lambda_\alpha^1) & \longmapsto & (q_1, q_2, q_3, q_4, \lambda_\alpha^1, \lambda_\alpha^2) \end{array}$$

which univocally determines q_4 and λ_α^2 , $1 \leq \alpha \leq m$ from the initial conditions $(q_0, q_1, q_2, q_3, \lambda_\alpha^0, \lambda_\alpha^1)$. Here, $\overline{\mathcal{M}}_d$ denotes the submanifold of $Q^4 = Q \times Q \times Q \times Q$

$$\overline{\mathcal{M}}_d = \{(q_0, q_1, q_2, q_3) \in Q^4 \mid \Phi_d^\alpha(q_0, q_1, q_2) = 0, \Phi_d^\alpha(q_1, q_2, q_3) = 0, 1 \leq \alpha \leq m\}.$$

The mapping Υ_d will be called the **discrete second-order vakonomic flow**.

Using similar techniques than in [4, 6], it is possible to show that, under the regularity assumptions, the discrete second-order vakonomic flow is symplectic and preserves momentum in the case when we have a Lie group action preserving the discrete lagrangian L_d and the constraint submanifold $\mathcal{M}_d$.

6.3. Application to optimal control of underactuated mechanical systems. In this section, we show that the discrete vakonomic approach of second order problem is an appropriate framework for discrete versions of optimal control problems of underactuated mechanical systems considered in Section 5 (see [28] for an alternative approach). The main application will be the explicit construction of geometric numerical integrators for this type of systems.

Let us take a discrete lagrangian $L_d : Q \times Q \rightarrow \mathbb{R}$ where $Q = Q_1 \times Q_2$ as in Section 5. Then, an element $(q_0^A, q_1^A) \in Q \times Q$ admits a global decomposition of the form $(q_0^a, q_0^\alpha, q_1^a, q_1^\alpha)$. Thus, we can consider the following **discrete underactuated mechanical system**

$$\begin{aligned} D_2^a L_d(q_{k-1}^A, q_k^A) + D_1^a L_d(q_k^A, q_{k+1}^A) &= u_k^a \\ D_2^\alpha L_d(q_{k-1}^A, q_k^A) + D_1^\alpha L_d(q_k^A, q_{k+1}^A) &= 0, \end{aligned}$$

$1 \leq A \leq n$, $1 \leq a \leq m$, $m+1 \leq \alpha \leq n$. Here $D_i^a L_d$ and $D_i^\alpha L_d$ represent the partial derivatives with respect to coordinates a and α , respectively.

The optimal control problem is determined prescribing the discrete cost functional

$$\mathcal{A}_d = \sum_{k=1}^{N-1} C(q_k^A, q_{k+1}^A, u_k^a)$$

with initial and final conditions q_0, q_1 and q_{N-1}, q_N , respectively.

Since the control variables appear explicitly the previous discrete optimal control problem is equivalent to the second-order discrete vakonomic problem determined by

$$\begin{aligned} \tilde{L}_d(q_{k-1}^A, q_k^A, q_{k+1}^A) &= C(q_k^A, q_{k+1}^A, D_2^a L_d(q_{k-1}^A, q_k^A) + D_1^a L_d(q_k^A, q_{k+1}^A)) \\ \Phi_d^\alpha(q_{k-1}^A, q_{k+1}^A, q_{k+2}^A) &= D_2^\alpha L_d(q_{k-1}^A, q_k^A) + D_1^\alpha L_d(q_k^A, q_{k+1}^A) = 0. \end{aligned}$$

Applying the techniques developed in Subsection 6.2 and assuming the regularity condition (6.5) we obtain the discrete flow

$$\Upsilon_d : \overline{\mathcal{M}}_d \times \mathbb{R}^{2m} \longrightarrow \overline{\mathcal{M}}_d \times \mathbb{R}^{2m}.$$

Example 6.1. The Discrete Cart-Pole System: (See Example 5.3)

Consider the following discrete Lagrangian $L_d : Q \times Q \rightarrow \mathbb{R}$ where $Q = \mathbb{R} \times \mathbb{S}^1$

$$\begin{aligned} L_d(x_{k-1}, \theta_{k-1}, x_k, \theta_k) &= \frac{1}{2} M \left(\frac{x_k - x_{k-1}}{h} \right)^2 \\ &+ \frac{1}{2} m \left[\left(\frac{x_k - x_{k-1}}{h} \right)^2 + 2 \left(\frac{x_k - x_{k-1}}{h} \right) l \cos \left(\frac{\theta_k + \theta_{k-1}}{2} \right) \left(\frac{\theta_k - \theta_{k-1}}{h} \right) + l^2 \left(\frac{\theta_k - \theta_{k-1}}{h} \right)^2 \right] \\ &- mgl \cos \left(\frac{\theta_k + \theta_{k-1}}{2} \right) - mgh \end{aligned}$$

where $\tilde{h}$ is the car height.

The discretized controlled Euler-Lagrange equations are

$$\begin{aligned} & (2x_{k+1} - x_k - x_{k+2})\left(\frac{M+m}{h^2}\right) \\ & + \frac{ml}{h^2} \left[\cos\left(\frac{\theta_{k+1} + \theta_k}{2}\right) (\theta_{k+1} - \theta_k) - \cos\left(\frac{\theta_{k+2} + \theta_{k+1}}{2}\right) (\theta_{k+2} - \theta_{k+1}) \right] = u_k \\ & \frac{l^2 m}{h^2} (2\theta_{k+1} - \theta_k - \theta_{k+2}) + \frac{lm}{h^2} \left[(x_{k+1} - x_k) \cos\left(\frac{\theta_{k+1} + \theta_k}{2}\right) - (x_{k+2} - x_{k+1}) \cos\left(\frac{\theta_{k+2} + \theta_{k+1}}{2}\right) \right] \\ & + \frac{lmg}{2} \left[\sin\left(\frac{\theta_{k+1} + \theta_k}{2}\right) + \sin\left(\frac{\theta_{k+2} + \theta_{k+1}}{2}\right) \right] \\ & - \frac{lm}{2h^2} \left[(x_{k+1} - x_k)(\theta_{k+1} - \theta_k) \sin\left(\frac{\theta_{k+1} + \theta_k}{2}\right) + (x_{k+2} - x_{k+1})(\theta_{k+2} - \theta_{k+1}) \sin\left(\frac{\theta_{k+2} + \theta_{k+1}}{2}\right) \right] = 0. \end{aligned}$$

For solving the associated discrete optimal control problem, we need to find sequences $\{(q_k, q_{k+1}, u_k)\}$, minimizing the cost functional

$$\mathcal{A}_d = \frac{1}{2} \sum_{k=1}^{N-1} u_k^2.$$

We know that this problem is equivalent to solve the following variational problem with constraints

$$\min \tilde{\mathcal{A}}_d = \sum_{k=0}^{N-2} \tilde{L}(x_k, \theta_k, x_{k+1}, \theta_{k+1}, x_{k+2}, \theta_{k+2})$$

subject to the constraints

$$\begin{aligned} & \Phi_d(q_k, q_{k+1}, q_{k+2}) = \\ & l^2 m (2\theta_{k+1} - \theta_k - \theta_{k+2}) + lm \left[(x_{k+1} - x_k) \cos\left(\frac{\theta_{k+1} + \theta_k}{2}\right) - (x_{k+2} - x_{k+1}) \cos\left(\frac{\theta_{k+2} + \theta_{k+1}}{2}\right) \right] \\ & + \frac{lmgh^2}{2} \left[\sin\left(\frac{\theta_{k+1} + \theta_k}{2}\right) + \sin\left(\frac{\theta_{k+2} + \theta_{k+1}}{2}\right) \right] \\ & - \frac{lm}{2} \left[(x_{k+1} - x_k)(\theta_{k+1} - \theta_k) \sin\left(\frac{\theta_{k+1} + \theta_k}{2}\right) + (x_{k+2} - x_{k+1})(\theta_{k+2} - \theta_{k+1}) \sin\left(\frac{\theta_{k+2} + \theta_{k+1}}{2}\right) \right] = 0, \end{aligned}$$

with $k = 0, \dots, N-2$ where $\tilde{L}_d : Q \times Q \times Q \rightarrow \mathbb{R}$ is given by

$$\begin{aligned} \tilde{L}_d(q_k, q_{k+1}, q_{k+2}) &= \frac{1}{2} u_k^2 \\ &= \frac{(M+m)^2}{2h^4} (2x_{k+1} - x_k - x_{k+2})^2 \\ &\quad + \frac{(ml)^2}{2h^4} \left[\cos\left(\frac{\theta_{k+1} + \theta_k}{2}\right) (\theta_{k+1} - \theta_k) - \cos\left(\frac{\theta_{k+2} + \theta_{k+1}}{2}\right) (\theta_{k+2} - \theta_{k+1}) \right]^2 \end{aligned}$$

To test our numerical algorithm we have programmed it in Matlab. The program admits as input data $(q_0, q_1, q_2, q_3, \lambda_0, \lambda_1)$ and the number of steps N ; then it computes q_4 and λ_2 and replace the initial data with $(q_1, q_2, q_3, q_4, \lambda_1, \lambda_2)$ to calculate q_5 and λ_3 , etc.

In the figure we show the excellent energy behavior (of the function H_{W_1}) of our symplectic geometric integrator for the cart-pole system
